

BigRIPS Separator at RIKEN

T. Kubo, K. Kusaka, Y. Mizoi, A. Yoshida and K. Yoshida/RIKEN

- Currently being built for the production of radioactive/rare isotope beams at RIKEN RI-beam factory (RIBF).
- **BigRIPS: In-flight RI-beam separator.**

1. Outline of RIKEN RI-beam factory project

(being built, first beam acceleration in 2006)

2. Outline of BigRIPS separator

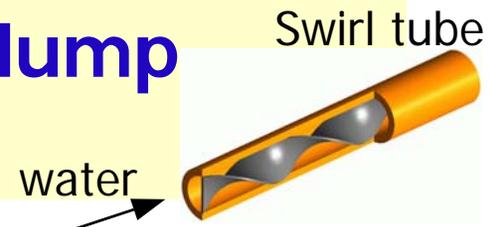

(being built, first RI-beam production in 2006)

High beam power
~100 kW max.

3. High-power water-cooled rotating target

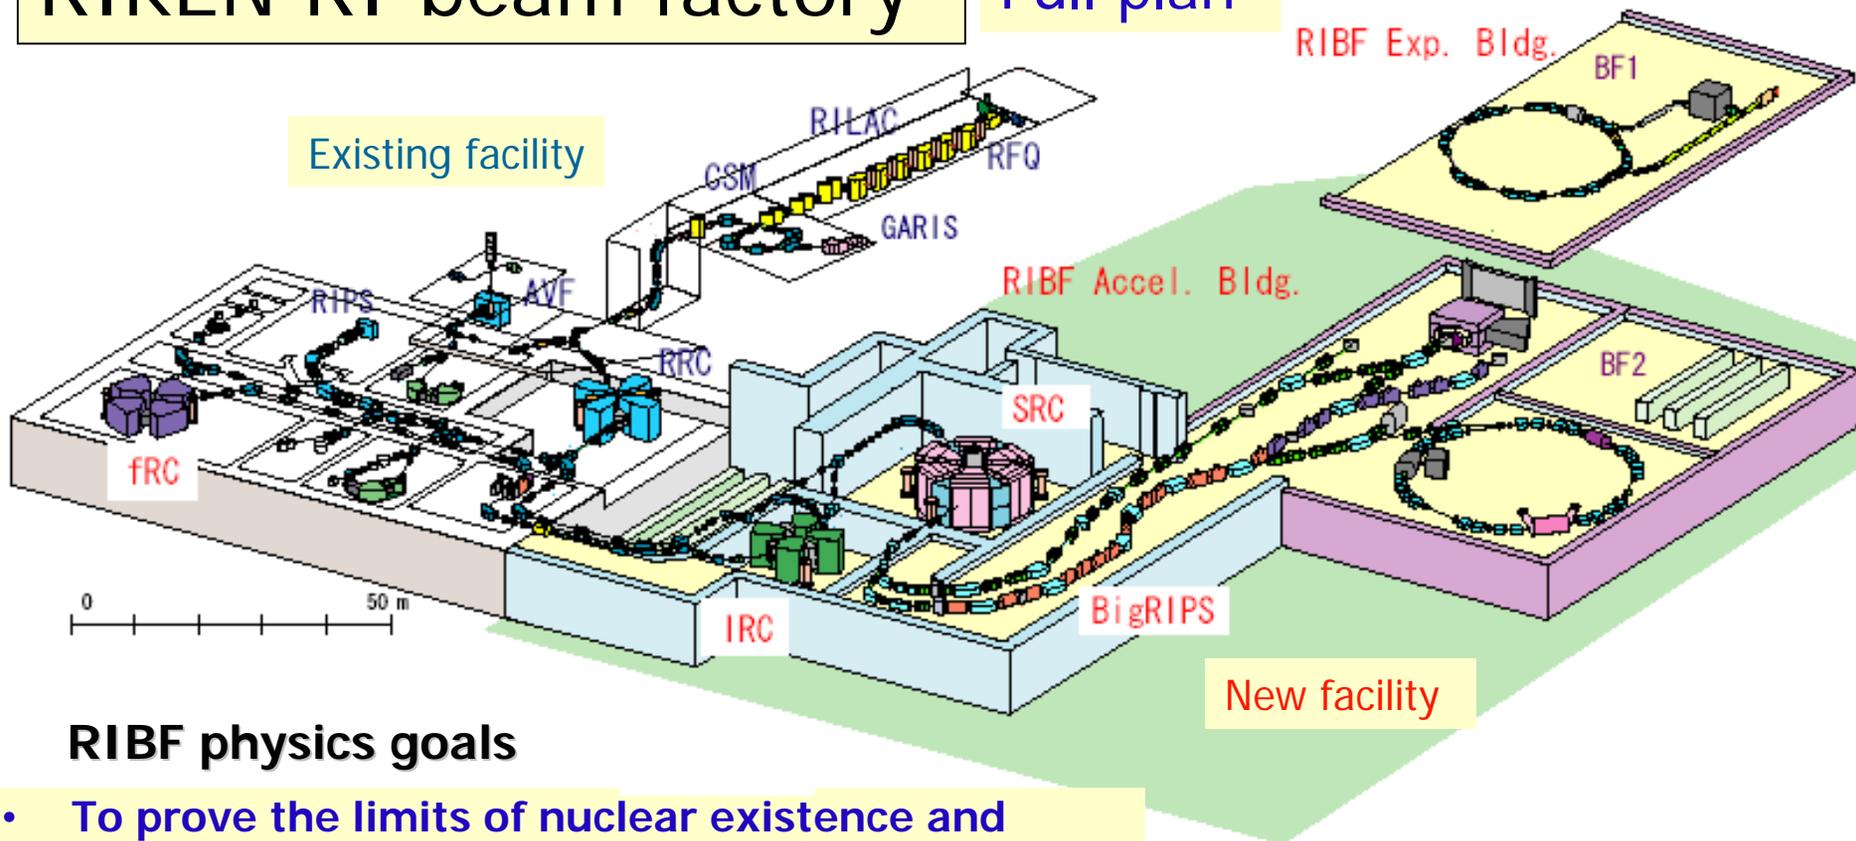

(being developed)

4. High-power water-cooled beam dump using swirl tubes (being designed)

RIKEN RI-beam factory

Full plan

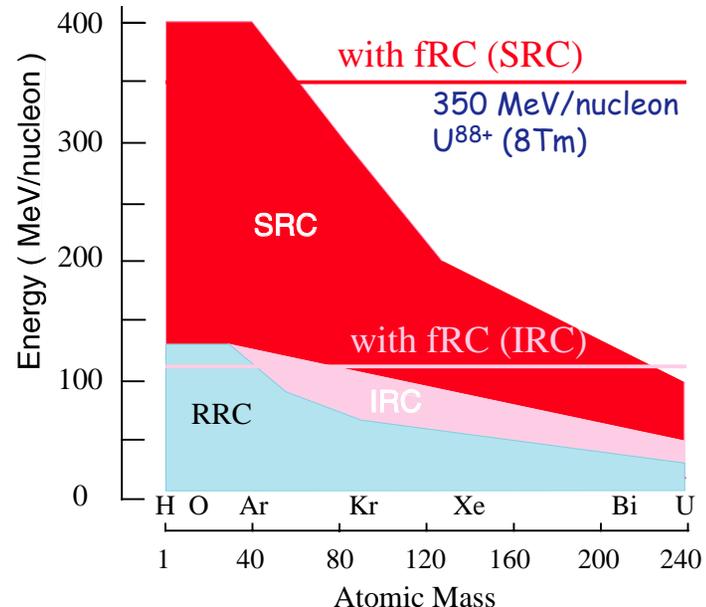

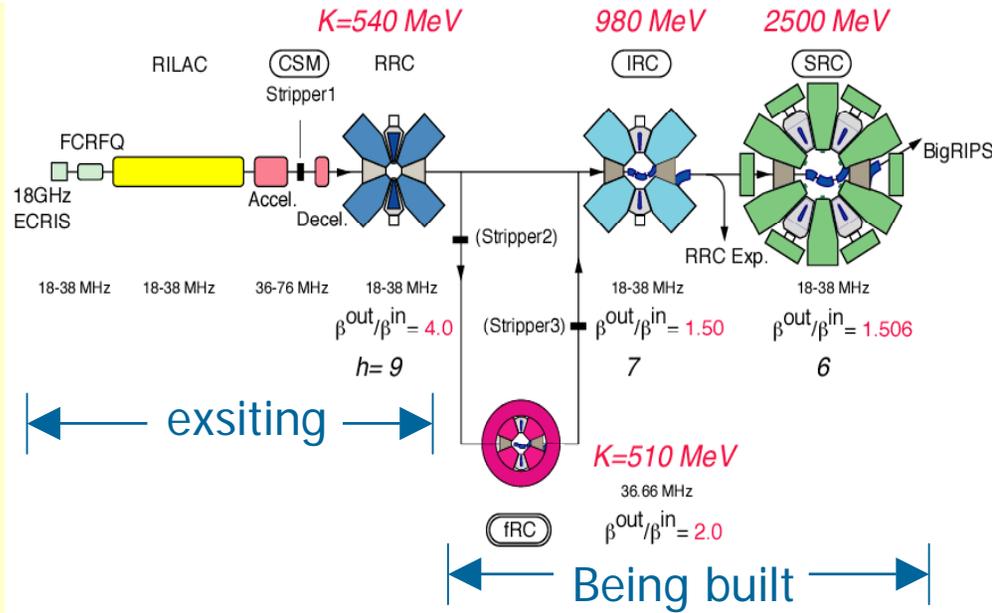

RIBF physics goals

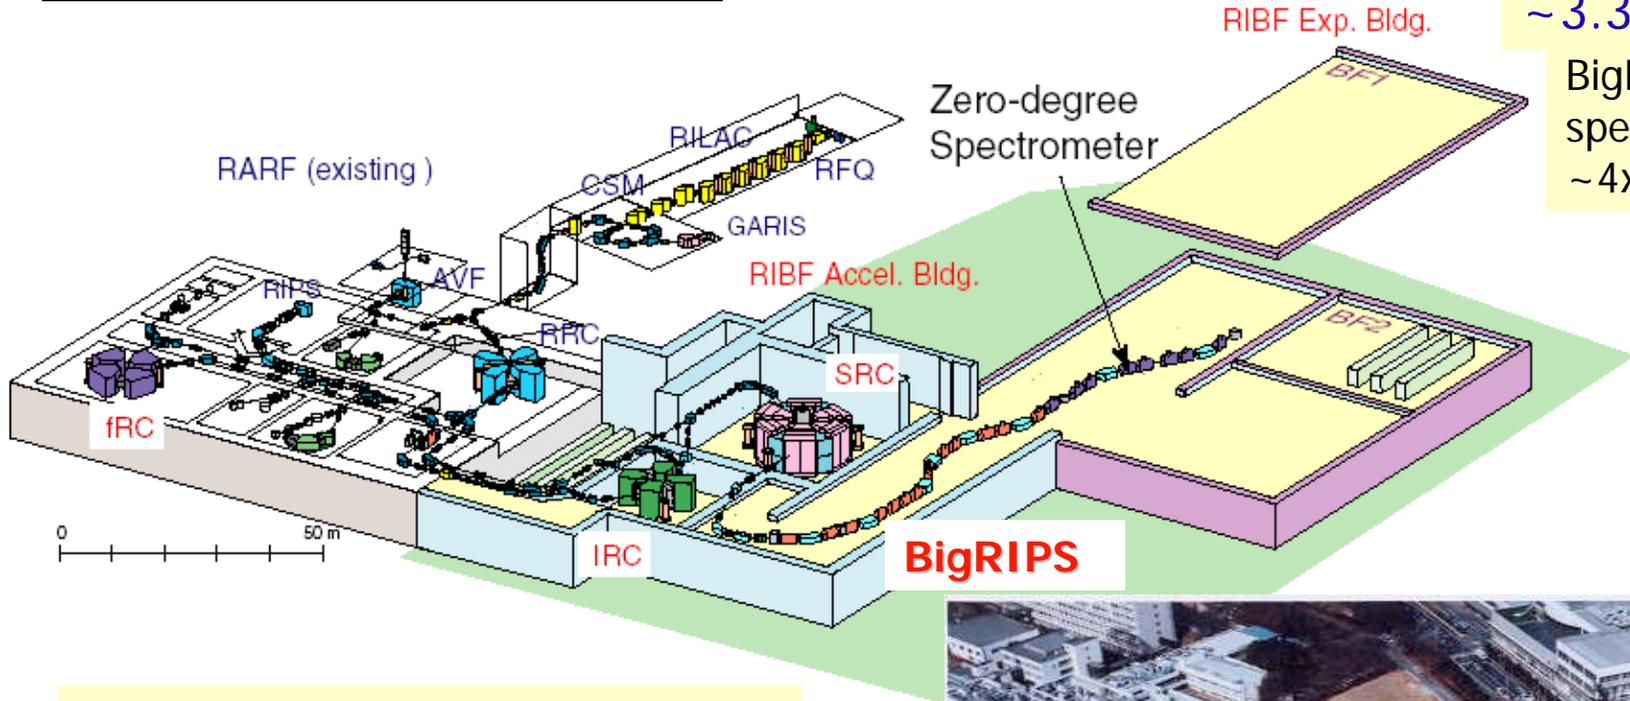

- **To prove the limits of nuclear existence and to understand the basic physics of the nuclear landscape**
 - Exploration of the limit of existence
 - Magic numbers far from stability
- **To explore the new forms and dynamics of nuclei**
 - Neutron skin and halo
 - Exotic shapes
- **To provide the basic data of nuclear astrophysics**
 - Stellar evolution and the rp-process
 - The r-process
 - Equation of state of asymmetric matter and neutron stars

Outline of RIKEN RI-Beam Factory (RIBF)

- Three new cyclotrons (fRC, IRC and SRC) are being built as an extension of the existing cyclotron facility.
- SRC: a superconducting cyclotron with $K = 2500$ MeV. 7800 tons.
- Cascade of the cyclotrons accelerates heavy ions up to 400 MeV/u for light $A (< 40)$, 350 MeV/u for heavy A up to ^{238}U .
- Expected max. beam intensity: $\sim 1 \mu\text{A}$ (6×10^{12} pps).
- Max. beam power: ~ 100 kW (^{238}U 350 MeV/u $\sim 1 \mu\text{A}$: goal)
- BigRIPS: production, separation and tagging of RI beams.
- RI-beam delivery lines and several experimental setups downstream of BigRIPS

RIBF layout in 2006

$\sim 40 \times 10^9$ yen
 $\sim 3.3 \times 10^8$ USD
BigRIPS+0-deg spectrometer:
 $\sim 4 \times 10^9$ yen

First beam acceleration & first RI-beam production: scheduled in 2006

Building → construction

Feb. 2003

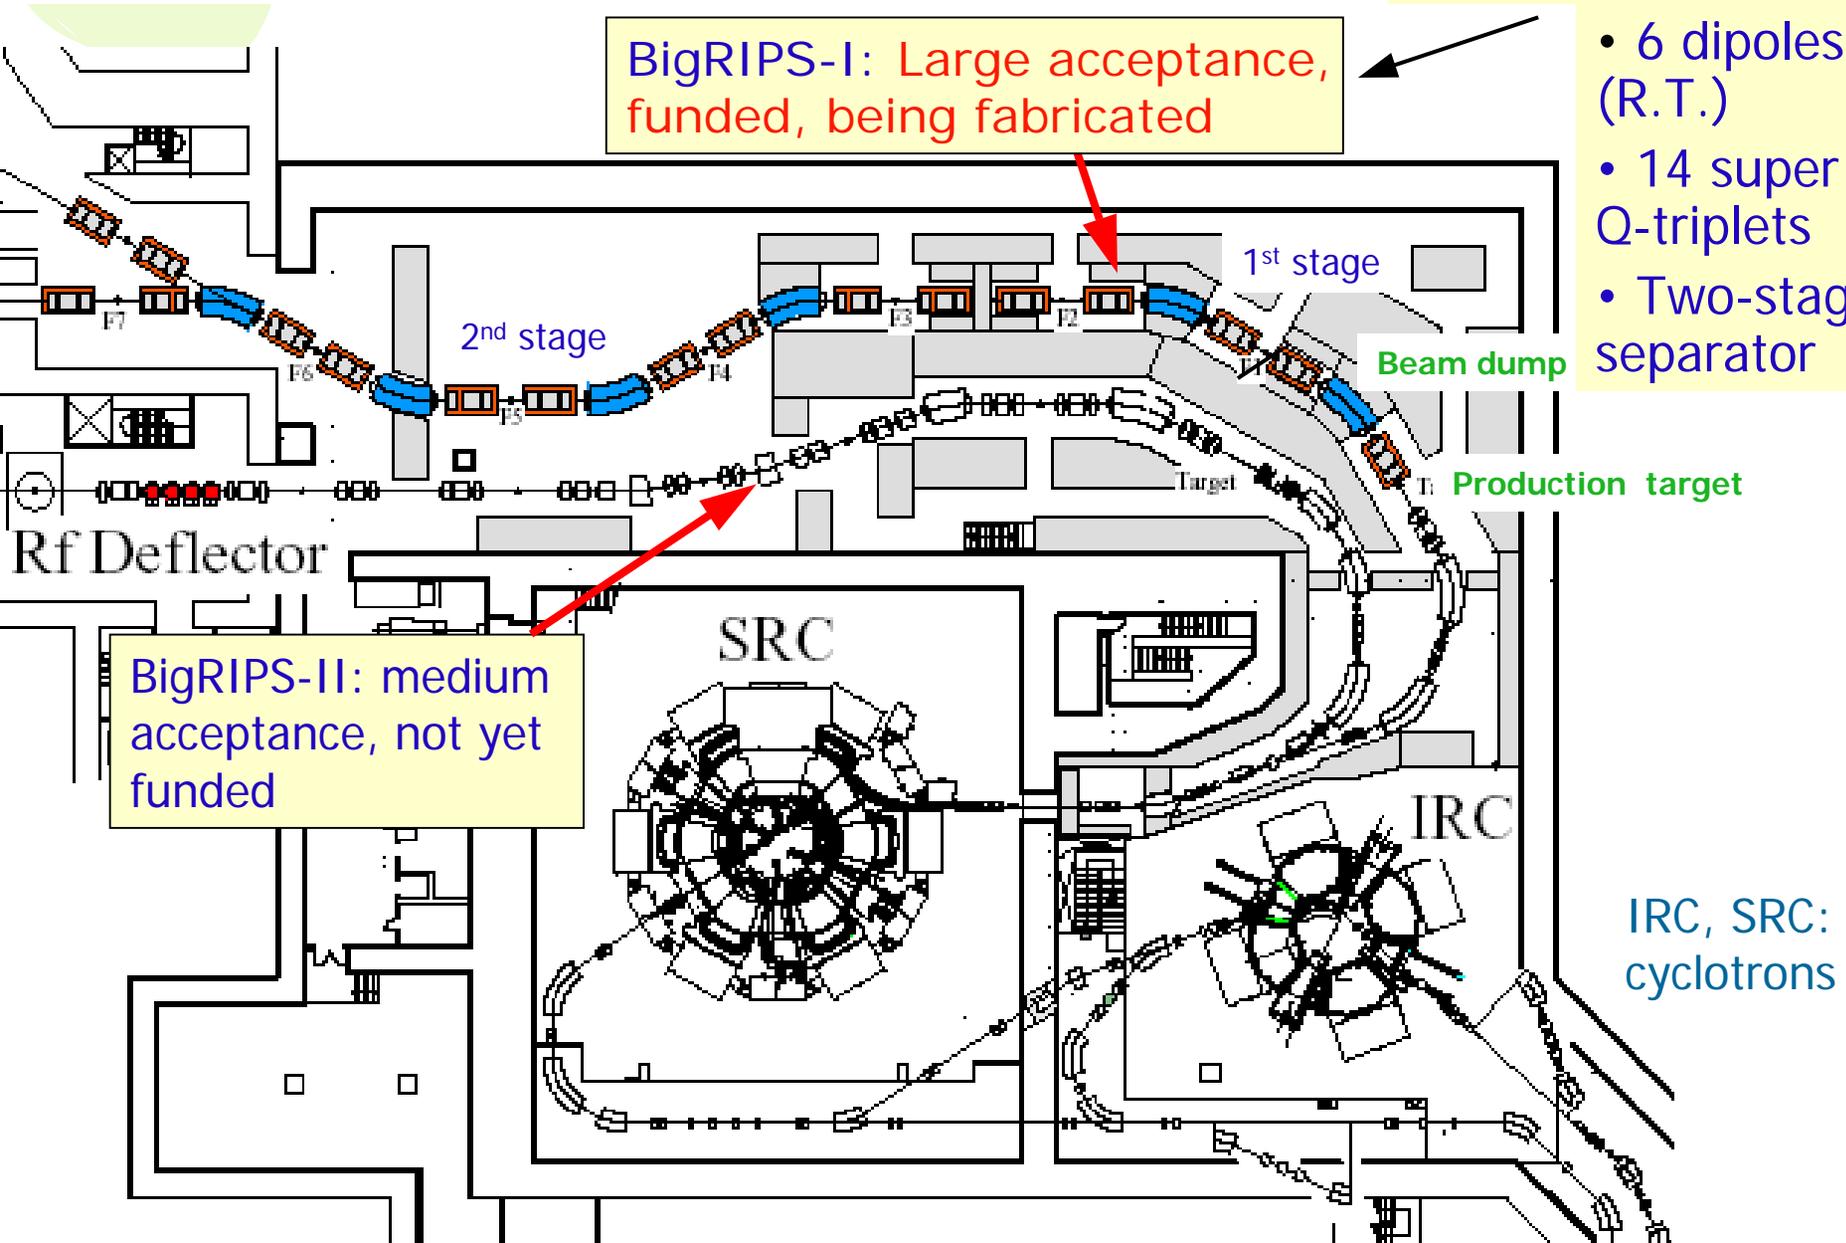

Layout of BigRIPS separator

Superconducting quadrupole triplets with large apertures

BigRIPS-I: Large acceptance, funded, being fabricated

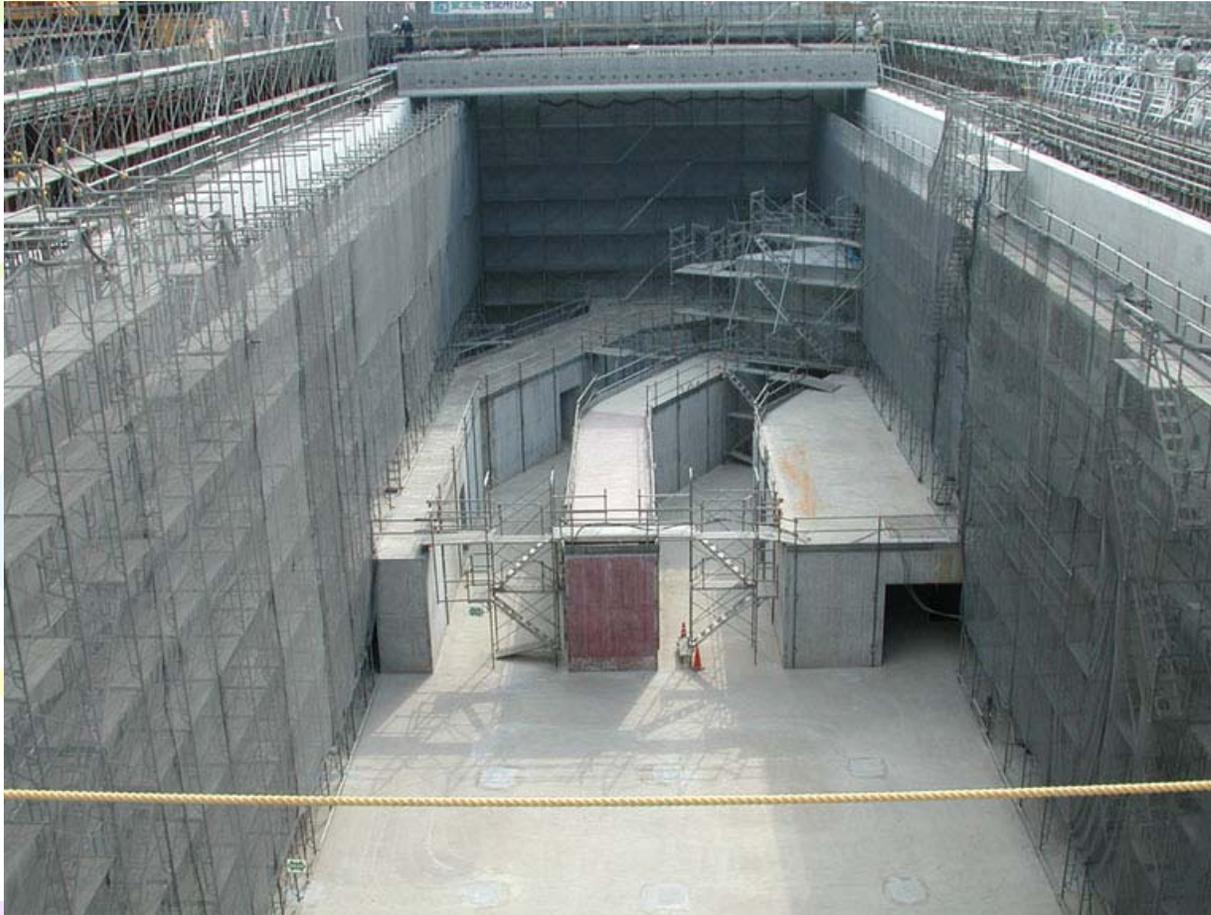

- 6 dipoles (R.T.)
- 14 super Q-triplets
- Two-stage separator

BigRIPS-II: medium acceptance, not yet funded

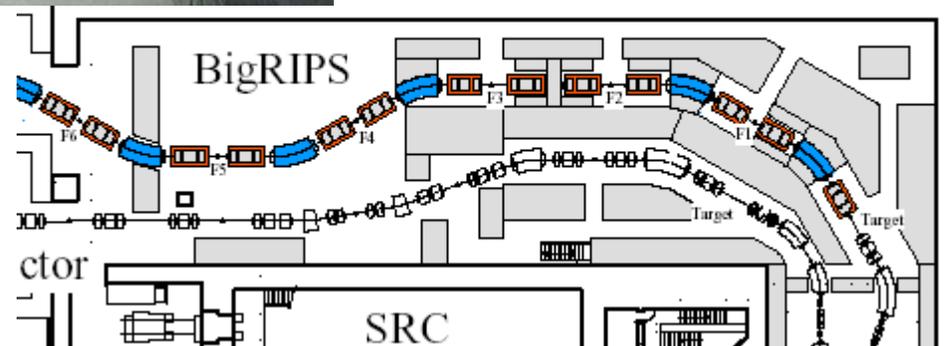

IRC, SRC: cyclotrons

Features of the BigRIPS separator

BigRIPS-I

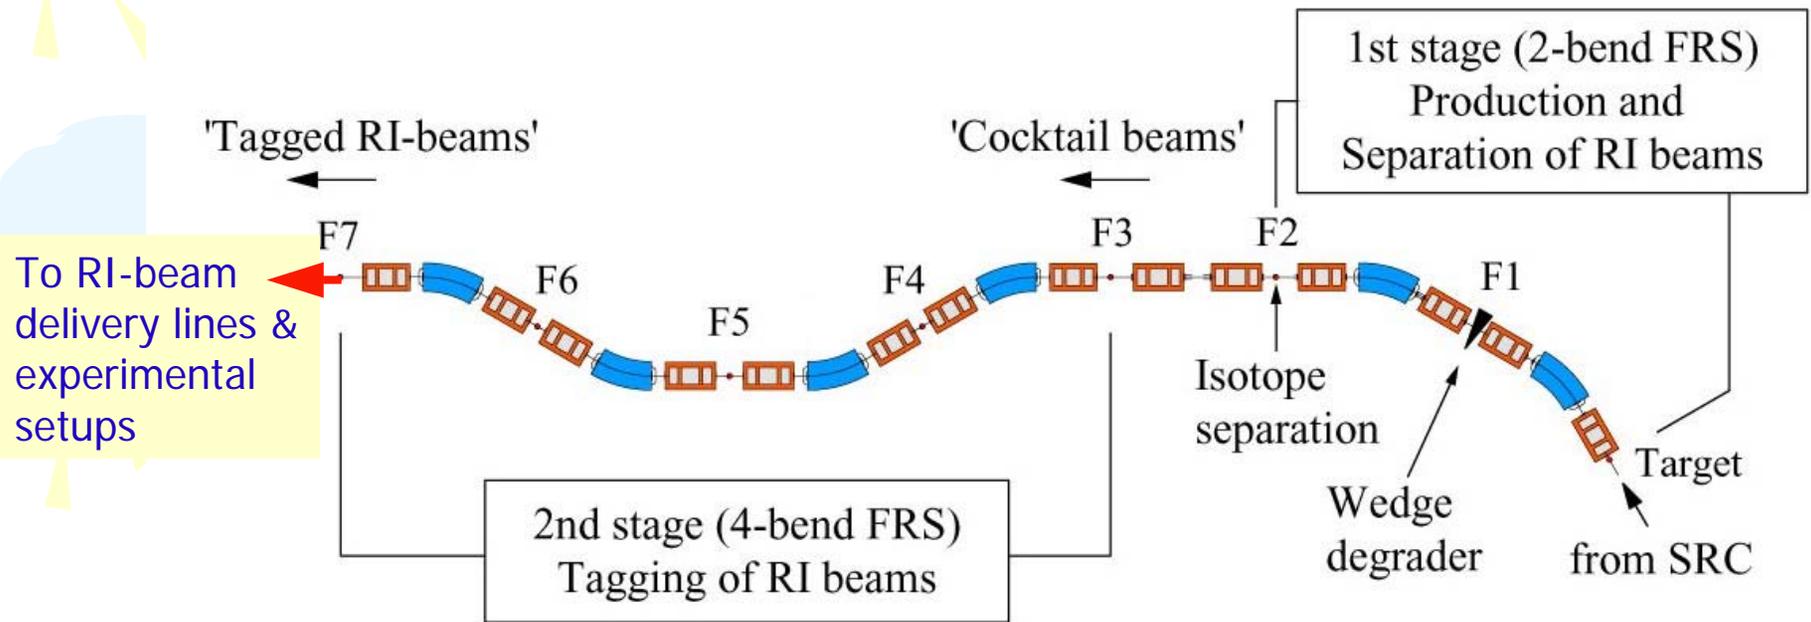

- In-flight fission of ^{238}U beams is used, as well as projectile fragmentation.
 - > Large cross section for medium heavy neutron-rich isotopes.
- Large acceptance: 80 – 100 mr, 6 %, allowing efficient collection of fission fragments which have large spreads at our energy, e.g. ~100 mr, ~10 % at 350 MeV/u.

- The large acceptance is achieved by using superconducting quadrupoles with a large aperture.
- RI-beam purity is still not so good at our energies: sometimes called 'Cocktail beams'.
- Two-stage separator scheme is adopted to overcome this difficulty: allows to deliver Tagged RI beams, and facilitates RI-beam experiments such as secondary reaction studies.
- Followed by RI-beam delivery lines and experimental setups.

Delivery of tagged RI beams

Superconducting quadrupole for BigRIPS, features

- **Quadrupole triplet:**
three quadrupoles are installed in a single cryostat.
- **Large aperture:**
warm bore radius of 120 mm,
-> large acceptance
- **Iron-dominated type:** STQ2-14,
partly **air-core type:** STQ1
- Thin **NbTi wire:** 1.1 mm ϕ
- **Impregnated coils** with epoxy
- Epoxy with a **filler**
- Wet and **orderly winding**
- **Flat coil**, a racetrack shape
- A prototype: successfully tested

2.5 W at 4.3 K (for each STQ)

GM-JT refrigerator

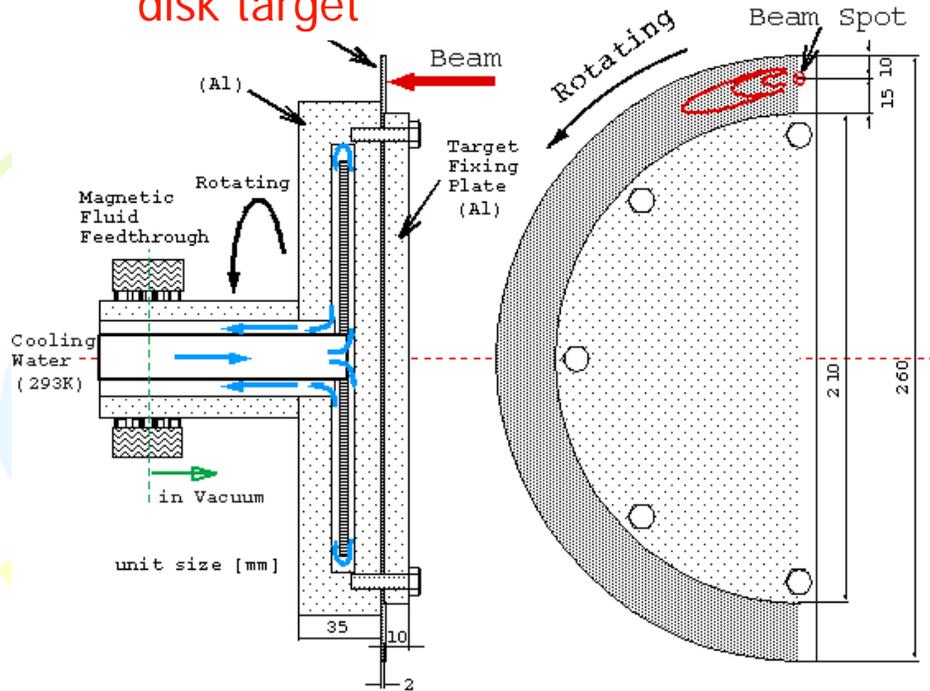

High-power water-cooled rotating-disk target

1. Max. beam power: ~ 100 kW (goal)
 ^{238}U 350 MeV/u ~ 1 μA
2. Target material: C, Be, Ta
3. Max. energy loss in target: ~ 25 kW
In-flight fission of ^{238}U at 350 MeV/u
Thickness: ~ 1 g/cm² (C 5.6 mm)
Beam spot size: 1 mm ϕ
-> Max. power density: ~ 30 GW/m²,
 ~ 5.7 kW/mm³
4. A wide range of thickness up to ~ 30 mm for projectile fragmentation.
5. Water-cooled rotating disk target:
Disk size ~ 260 mm ϕ or smaller
Rotation speed: > 200 rpm
Water cooled (& partially radiation)
<- supplied through a rotation shaft

change thickness

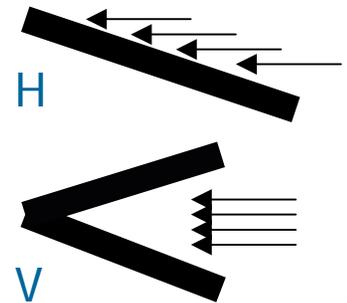

High-power water-cooled beam dump

- Beam power: ~ 100 kW max., ^{238}U 350 MeV/u 1 μA .
- Beam stops at the beam dump wall placed inside the first dipole.
- Stopping position and beam size changes depending on $B\rho$ setting.
- Power density amounts to \sim several hundreds MW/m^2 , if the beam is injected perpendicularly to the wall. Too high to cool!

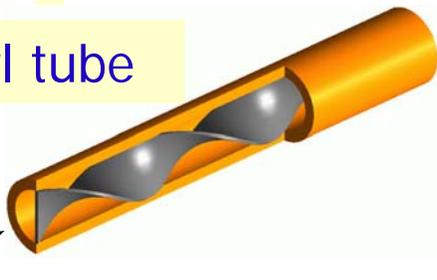

The power density can be reduced down to $\sim 20\text{-}50$ MW/m^2 in our case, because the beam is injected at small angles to the beam-dump wall and if the wall is vertically tilted like a V shape. This increases the projected beam-spot size. But still quite high density!

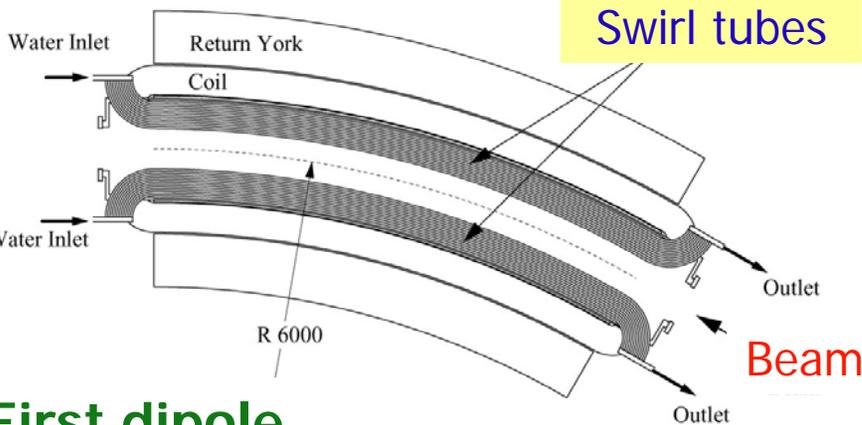

A swirl tube

water

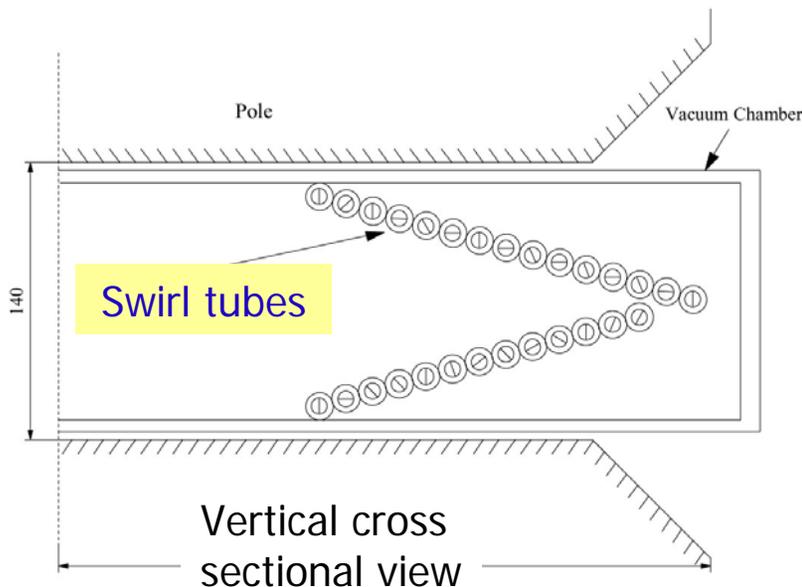

Water-cooled beam dump using a Cu swirl tube

Swirl tubes

First dipole

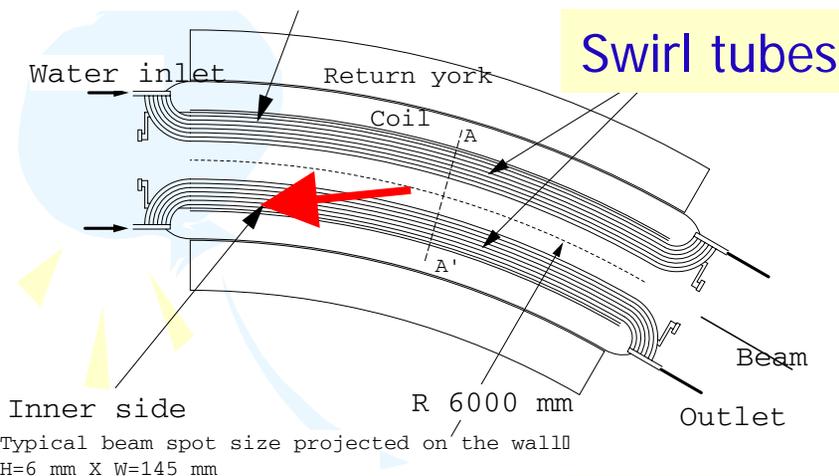

- Use swirl tubes for the beam-dump wall to improve the heat transfer coefficient h [W/m²K] of water by a factor of 2, allowing to lower the beam-dump temperature.
- Cooled by forced convection of pressurized water flow and latent heat of sub-cooled boiling.
- Swirl tubes promote turbulence flow, increasing h [W/m²K].
- Increase water pressure to increase the temperature margin.
- Material of tubes: CuCrZn alloy. Enhance the strength at high T, keeping heat conductivity the same. Material of swirl ribbon : INCONEL

ANSYS simulation for the Cu swirl-tube beam dump

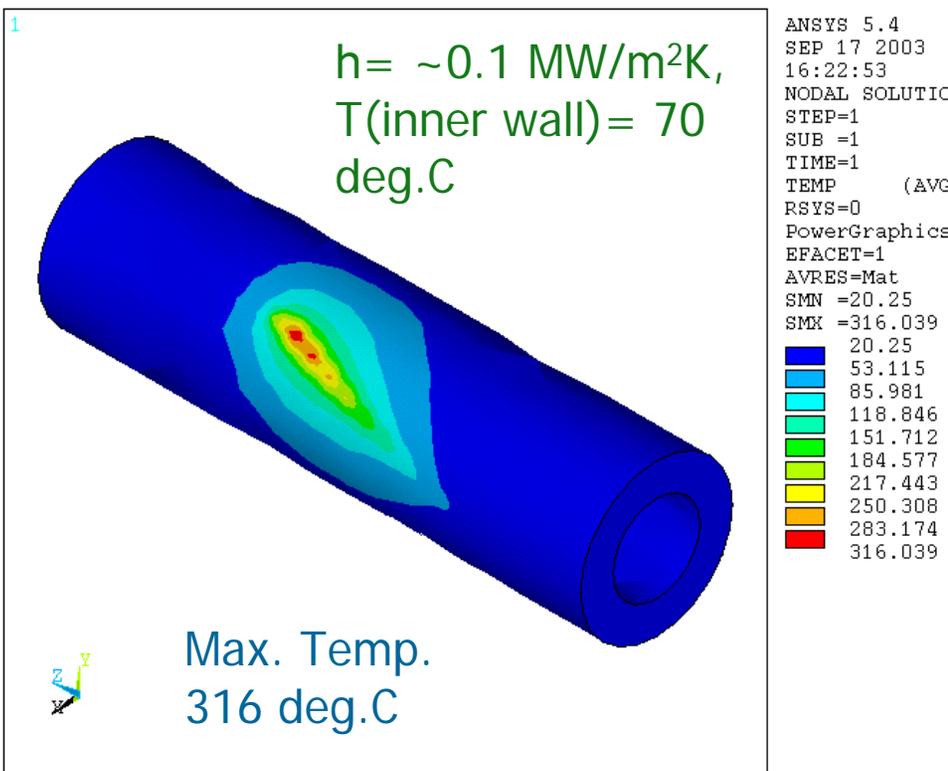

The beam hits the inner side: production of neutron-rich RI beams

Swirl tube conditions:
 $\phi(\text{out}) = 14 \text{ mm}$, $\phi(\text{in}) = 8 \text{ mm}$;
 material CuCrZn alloy ($\lambda = 351 \text{ W/mK}$).
 Water conditions:
 flow speed = 10 m/s; pressure = 10 atoms;
 boiling temp. = 180 degree C.

Vertically tilted angle:
 $\pm 9.8 \text{ deg.}$

Average density:
 $\sim 46 \text{ MV/m}^2$

Well below the melting temp. of Cu.
 (1083 degree C)

Prototype of the swirl-tube beam dump for testing

Four swirl tubes

Ion beam/Laser beam

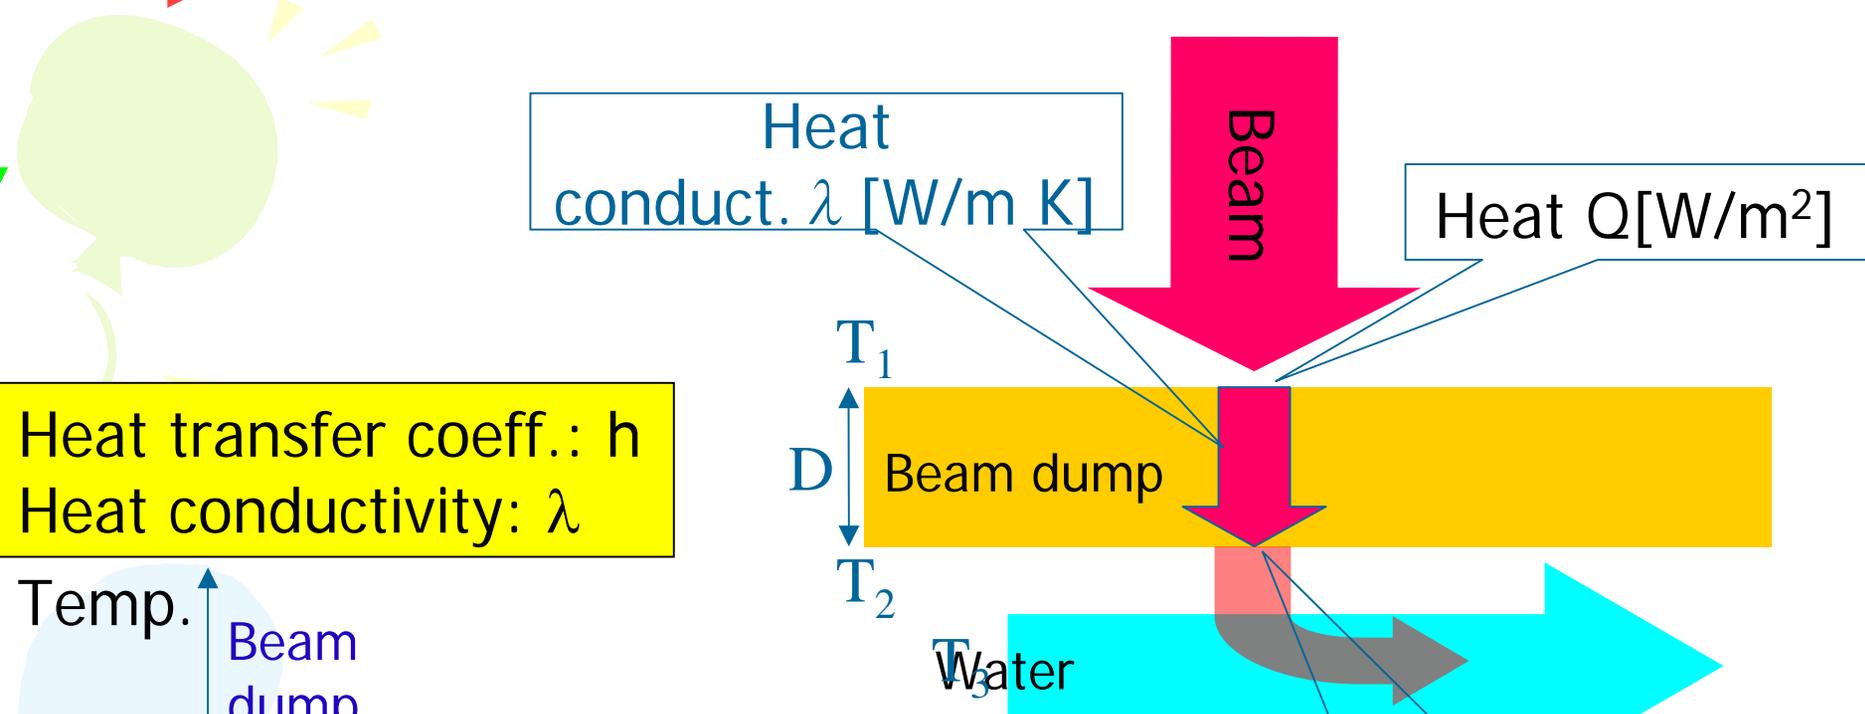

Recently built.

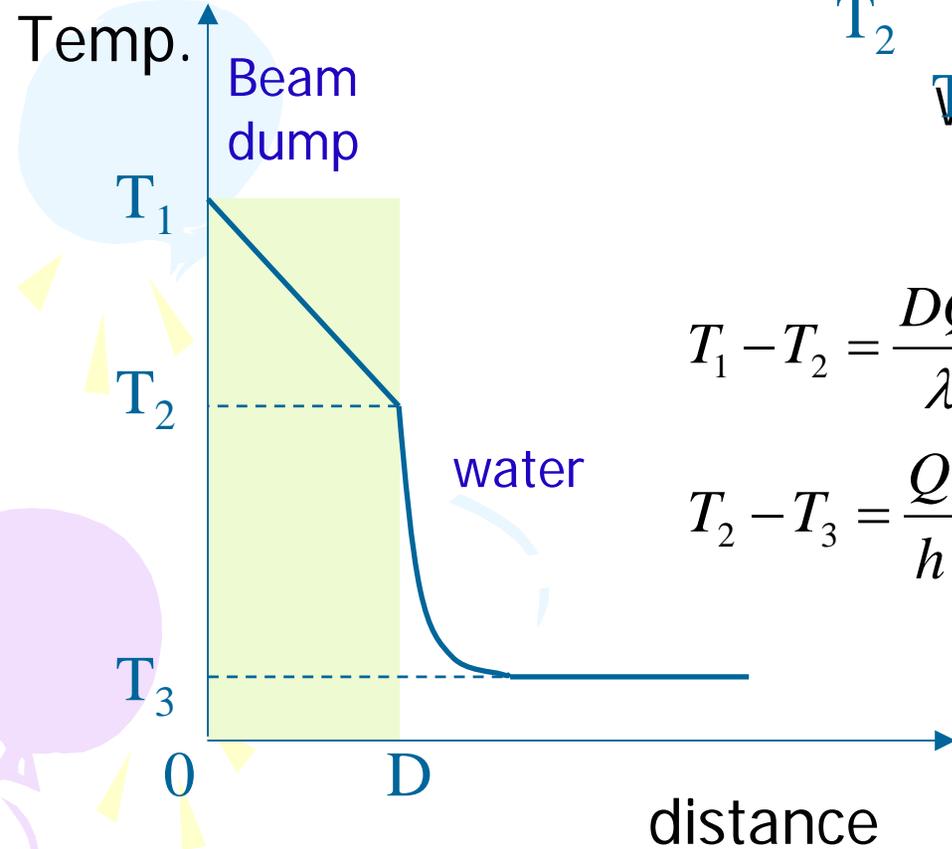

- Goal power density: $\sim 20\text{-}50 \text{ MW/m}^2$.
- Use of Cu swirl tube. $\phi(\text{out})$ and $\phi(\text{in})$ diameters: 14 mm and 8 mm. Swirl pitch; 16 mm. tube material: CuCrZn alloy ($\lambda=351 \text{ W/mK}$). Swirl ribbon material: INCONEL (Ni+Cr+etc).
- Water flow conditions: flow speed 10 m/s; pressure 10 atoms; boiling temp. 180 degree C; in sub-cooled boiling phase.
- Under these conditions, heat transfer coeff. $h= 0.1\text{-}0.3 \text{ MW/m}^2\text{K}$.
- Simulation by ANSYS shows it can withstand $20\text{-}50 \text{ MV/mm}^2$.
- Plan to test the prototype with a 6kW CW laser beam and ion beams at RIKEN. e.g. 1.8 kW Ar beams: beam size 1 cm x 1cm -> 18 MW/m^2 .

Summary

- 1) RIKEN RI-beam factory (RIBF) **First beam in 2006**
Three new cyclotrons are being built. $E = 400 \text{ MeV/u}$ for $A < 40$ and 350 MeV/u for heavier A up to U . $I = 1 \text{ p}\mu\text{A}$.
- 2) In-flight RI beam separator BigRIPS **First RI beam in 2006**
 - > **Large acceptances**: efficient RI beam production for in-flight fission
 - > **Two-stage separator scheme**: delivery of tagged RI beams
 - > **Large-aperture superconducting quadrupoles**
 - > etc.
- 3) High-power water-cooled rotating disk target
being developed. $\sim 25 \text{ KW}$, 5.7 kW/mm^3 , 30 GW/m^2 at max.
ANSYS simulation and beam testing show that this type of target can withstand the beam heat loads of $\sim 25 \text{ kW}$.
- 4) High-power water-cooled beam dump using a swirl tube
being developed. $\sim 100 \text{ kW}$, $\sim 20\text{-}50 \text{ MW/m}^2$ at max. A prototype
using has been built recently and is to be tested soon.
ANSYS simulation shows it can withstand the expected power density.

Heat transfer coeff.: h
Heat conductivity: λ

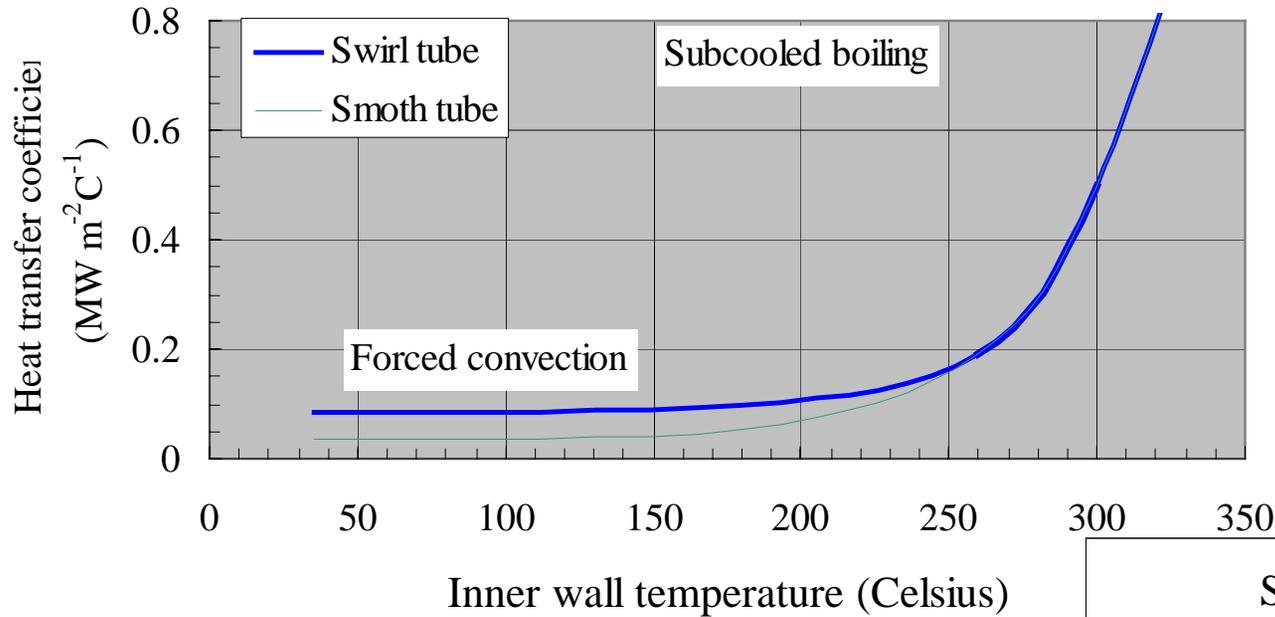

$$T_1 - T_2 = \frac{DQ}{\lambda}$$

$$T_2 - T_3 = \frac{Q}{h}$$

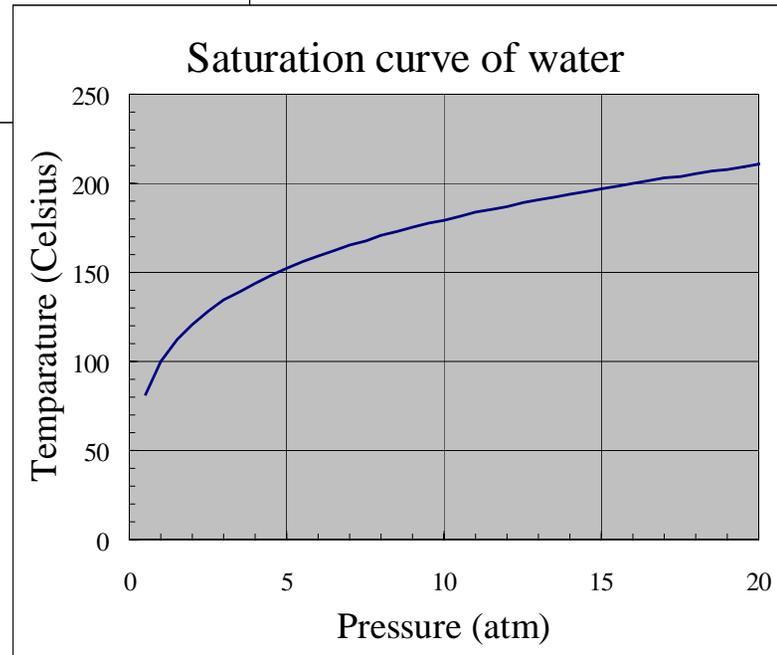

Heat transfer coeff.
 $h[W/m^2K]$

Heat transfer coefficient for BigRIPS swirl tube calculated by JAERI formula

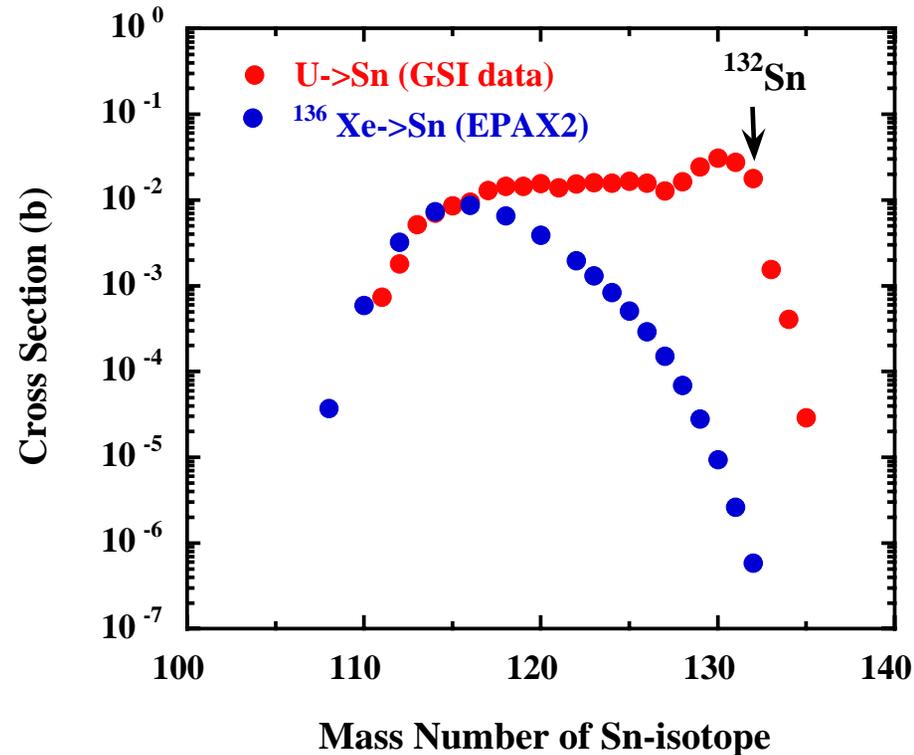

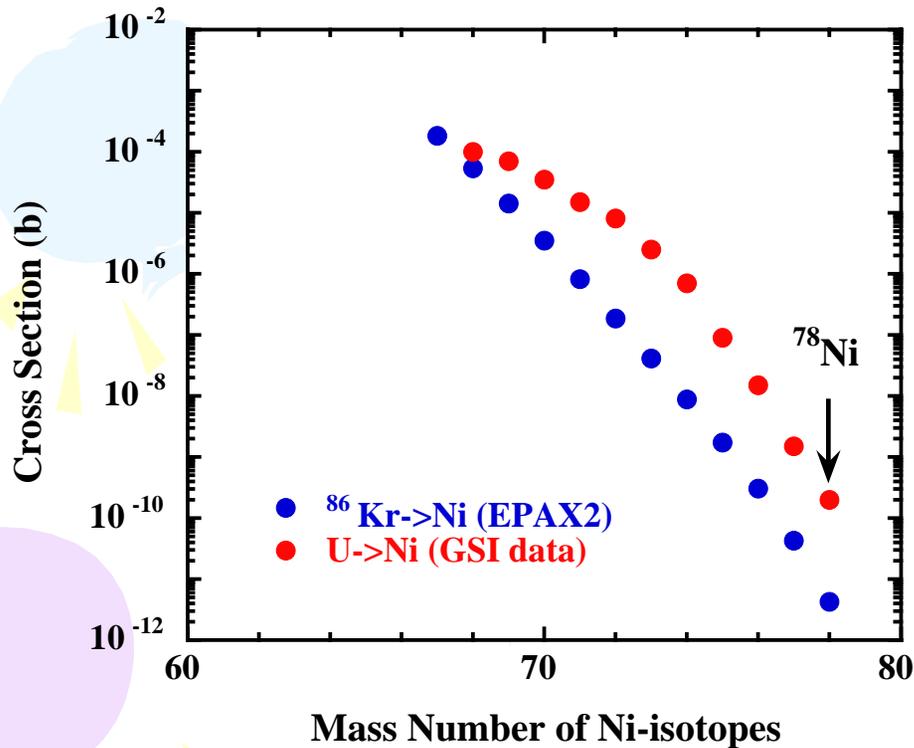

Heat transfer coefficient: h v.s. Inner wall temp. of tube

Swirl tube parameters:
 $\phi(\text{out}) = 14 \text{ mm}$, $\phi(\text{in}) = 8 \text{ mm}$;
material CuCrZn alloy ($\lambda = 351 \text{ W/mK}$).
Water conditions:
flow speed = 10 m/s; pressure = 10
atms; boiling temp. = 180 degree C.

Productin cross section of Ni and Sn isotopes

Radiation damages caused by fast neutrons from the target and beam dump

- **Radiation damages** to the components closely located.
avoid using weak materials and choose stronger or the strongest ones that are currently available.
e.g. polyimid coating for the NbTi wire, a polyimid super-insulator foil, full mineral insulated r.t. coils for the first dipole and so on.
- The first two quadrupole triplets (STQ1 and STQ2) may be destroyed in a few years mainly due to the damage to coil epoxy.
Replace them by new one. Designing BigRIPS so that the replacement can be made as easily as possible under high residual radiation.

Radiation heat loads to the cryogenic system of STQ1-5

Particularly the first two quadrupole triplets STQ1 and STQ2.

(STQ1: an air-core type reduces the heat loads.)

Extra-cooling capacity: 270 W at 4.5 K v.s. normal loads: 150 W

Total cooling capacity: 420 W at 4.5 K with liquid nitrogen.

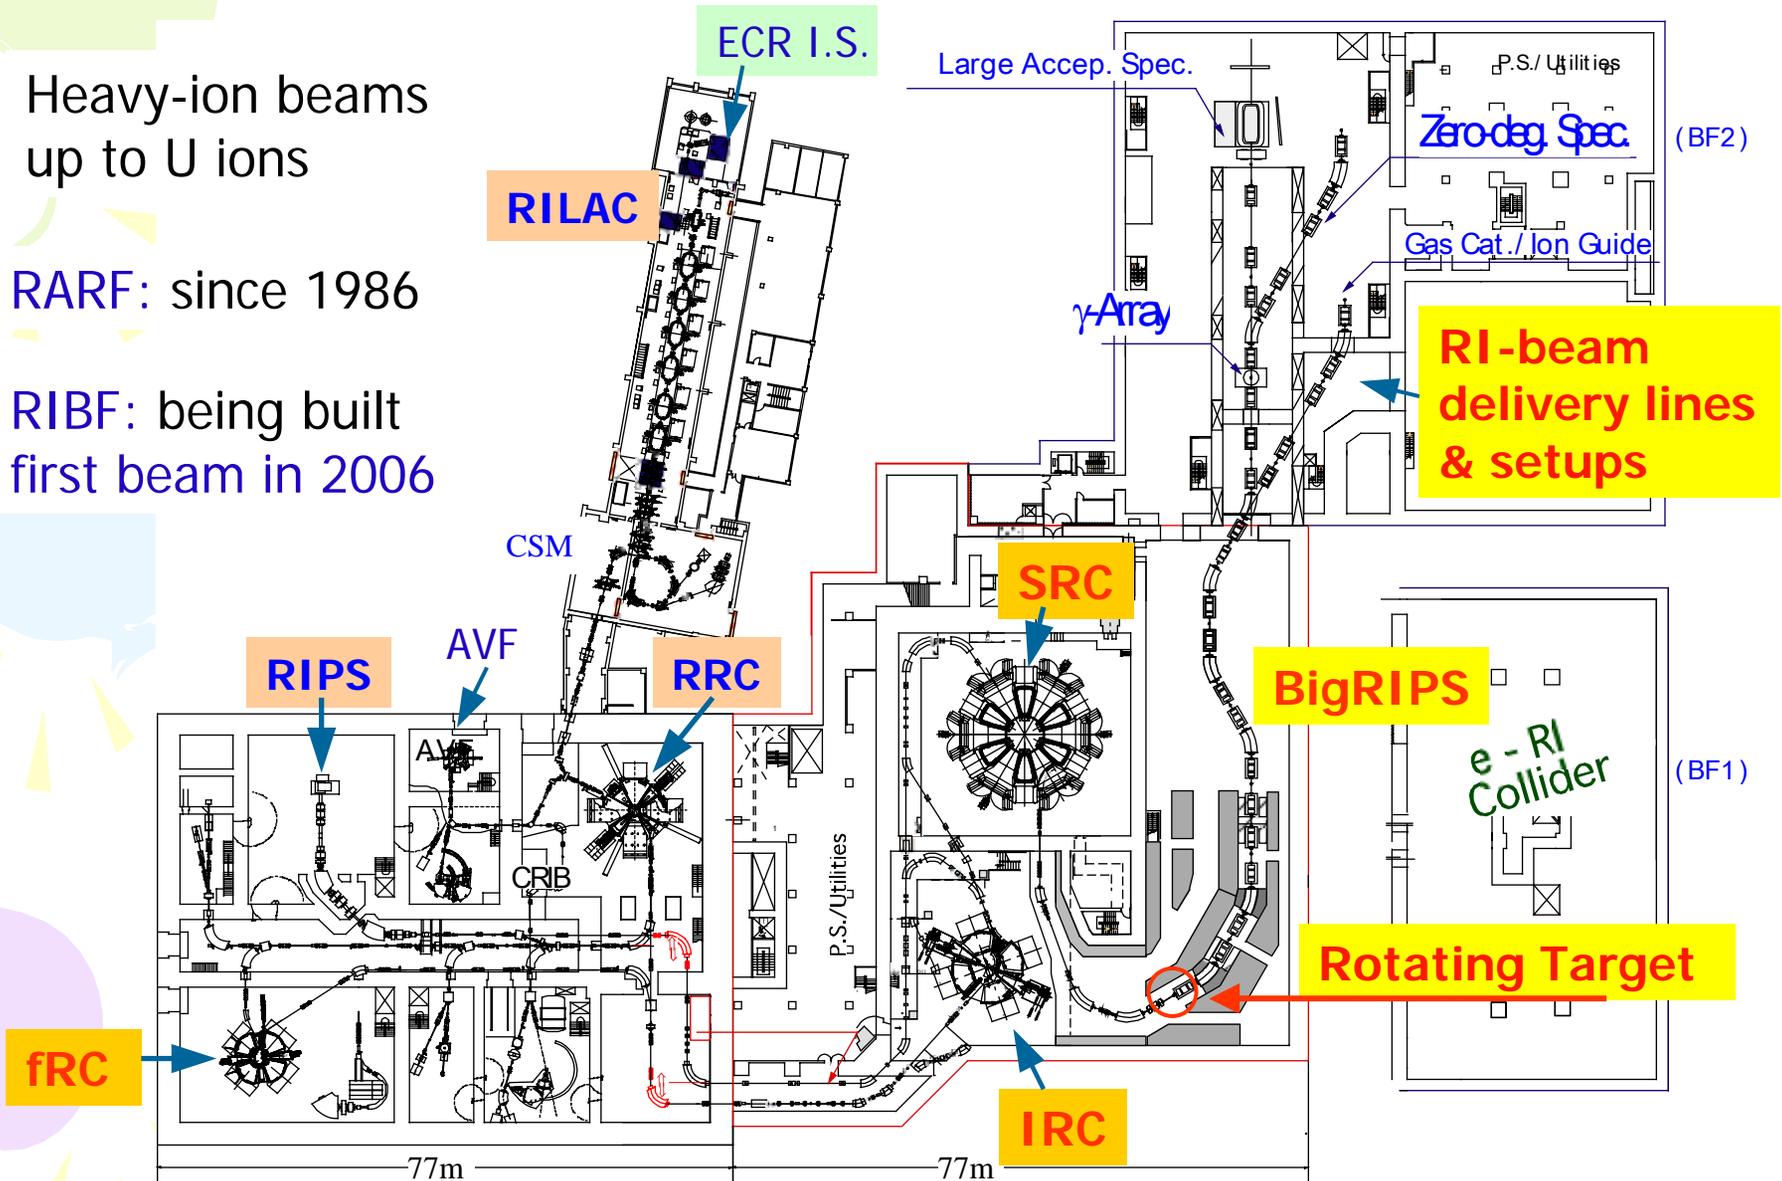

Heaters compensate the changes of radiation heat loads.

Heavy-ion beams
up to U ions

RARF: since 1986

RIBF: being built
first beam in 2006

Physics goal of RIKEN RI-beam Factory

- **To prove the limits of nuclear existence and to understand the basic physics of the nuclear landscape**

Exploration of the limit of existence

Drip-line nuclei: new-isotope search, mass

Nuclei outside the drip lines: (d, p), (p, ^2He)

Magic numbers far from stability

mass, β - γ , β - γ -n, moments (μ , Q)

Coulomb excitation, transfer reactions (d, p), (d, n)

nucleon knockout reactions (p, 2p), (p, pn)

charge exchange reactions (p, n), (d, 2n)

- **To explore the new forms and dynamics of nuclei**

Neutron skin and halo

total cross section, laser spectroscopy, elastic scattering

giant resonances: Coul. ex., (p, p'), (α , α')

Exotic shapes

multiple-Coulomb excitation

Physics goal of RIKEN RI-beam Factory (continued)

- **To provide the basic data of nuclear astrophysics**

- Stellar evolution and the rp-process

- Coulomb breakup (γ, p),

- transfer reaction (d, n)

- The r-process

- mass, $T_{1/2}$, Pn, β - γ -n,

- transfer reaction (d, p),

- Coulomb dissociation (γ, n)

- Equation of state of asymmetric matter and neutron stars

- Total cross section

- mono-pole giant resonance

Challenge toward the drip-lines

- How do nuclear properties change in large isospin asymmetry?

Location of the drip-lines

Shell structure, effective interactions

magicity loss at $N = 8, 20, 28, 50?, 82?, \dots$

new magic number at $N = 16, 34?, ?, \dots$

Odd-odd $N=Z$ nuclei, $T=0, T=1$

Nuclear matter and dynamics

Halo, skin

Exotic-cluster formation

EOS

- Challenge in predictions

Enhancement of prediction power

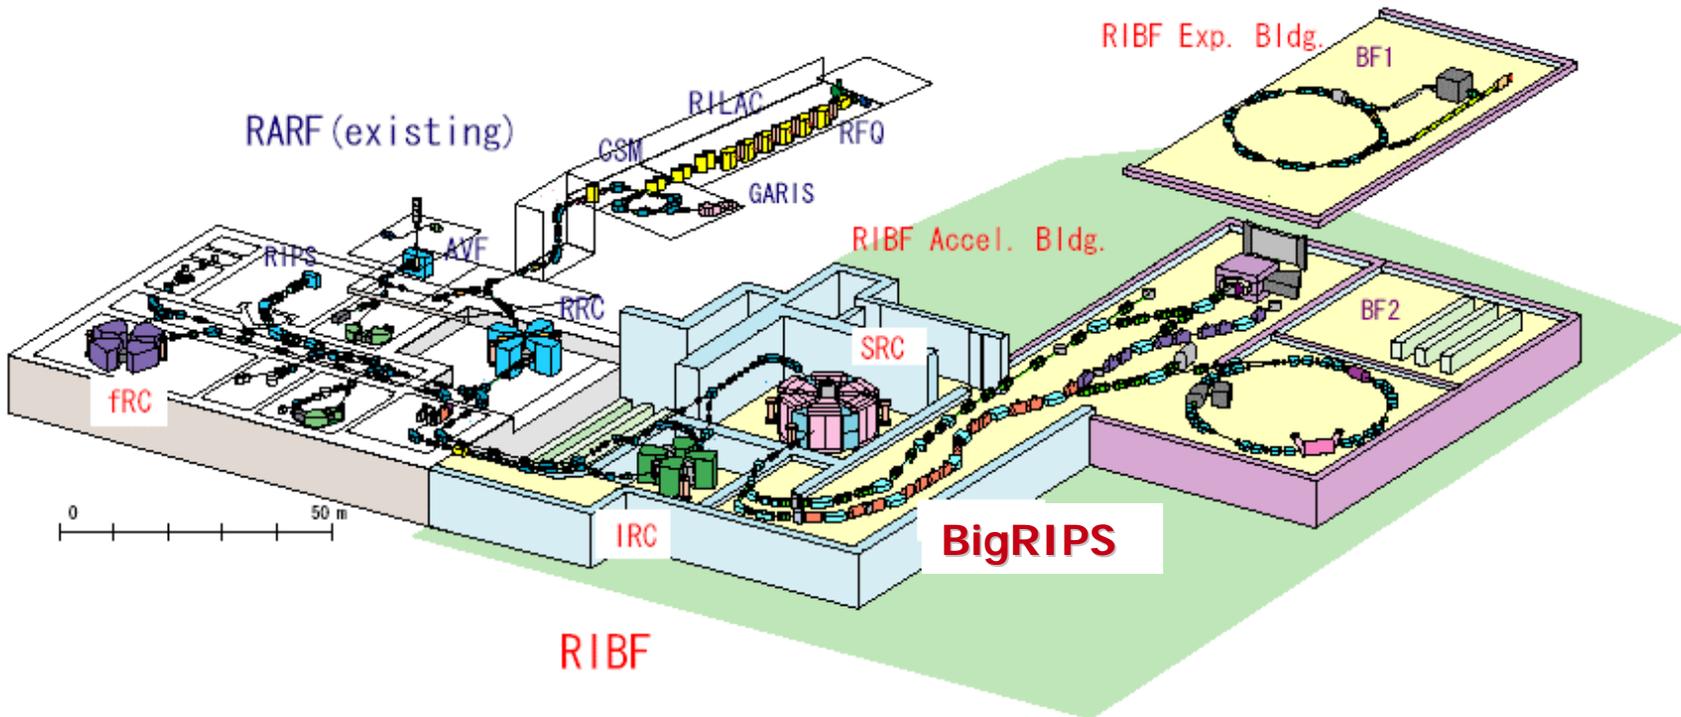

Exotic phenomena

- Challenge in measurements

Efficient production RI beams

New methods to overcome difficulties caused by low-yield rates
